Gender: F
MRN: Felf5484

RIGHT SHOULDER MRI WITHOUT CONTRAST

HISTORY: Right shoulder pain status post motor vehicle accident

TECHNIQUE: Multiplanar, multi-sequence MRI of the right shoulder was performed without intravenous contrast.

COMPARISON: None available.

FINDINGS:

ROTATOR CUFF: There are high-grade interstitial tears of the supraspinatus and infraspinatus tendons superimposed on tendinitis. Subscapularis and teres minor tendons are intact.

MUSCLES: No muscle edema or fatty muscle atrophy.

AC JOINT: There is mild to moderate acromioclavicular joint disease with marginal osteophytes which exert mass-effect on the supraspinatus myotendinous junction. There is thickening of the coracoacromial ligament which also contributes to rotator cuff impingement.

BICEPS TENDON: Intact long head of the biceps tendon.

LABRUM/LIGAMENTS: There is attenuation and irregularity of the posterior glenoid labrum consistent with labral tear best seen on image 8 of the axial oblique series 4.

GLENOHUMERAL CARTILAGE: Intact articular cartilage.

SYNOVIUM/JOINT FLUID: No joint effusion or synovial thickening.

MARROW: Normal marrow signal.

NEUROVASCULAR STRUCTURES: Normal in course and caliber.

PERIPHERAL SOFT TISSUES: Normal.

IMPRESSION:

High-grade interstitial tears of the supraspinatus and infraspinatus tendons superimposed on tendinitis. Evidence of rotator cuff impingement secondary to acromioclavicular joint disease and thickening of the coracoacromial ligament.
