Dear Dr. Barakat:

MRI OF THE RIGHT SHOULDER

Multiplanar, multisequence, multiecho MRI examination was performed through the right shoulder without intravenous contrast using a low field MRI.

The humeral head is well positioned within the glenoid. The glenohumeral joint appears intact.

There is a slightly curved acromion process with an intact acromioclavicular joint. There is no significant subacromial impingement. There is an Os acromiale without signal changes at the synchondrosis.

There is no acute fracture, suspicious intrinsic lesion, or evidence of osteonecrosis.

There is some signal abnormality in the distal supraspinatus tendon consistent with partial **tearing/tendinosis** without retraction. The infraspinatus, teres minor, and subscapularis tendons appear intact as does the long head of the biceps tendon.

The muscles are unremarkable.

There is no significant joint effusion nor significant fluid/synovitis of the subacromial or subdeltoid bursa.

No labral tears are appreciated on these images.

MRI OF THE RIGHT SHOULDER

IMPRESSION:

1. Partial tear/tendinosis of the supraspinatus tendon without retraction.
2. Os acromiale without signal changes at the synchondrosis.

Thank you for this referral.
