LEFT SHOULDER MRI WITHOUT CONTRAST

HISTORY: Left shoulder pain status post motor vehicle accident

TECHNIQUE: Multiplanar, multi-sequence MRI of the left shoulder was performed without intravenous contrast.

COMPARISON: None available.

FINDINGS:

ROTATOR CUFF: There is a linear interstitial tear at the attachment of the subscapularis tendon. There is supraspinatus, infraspinatus, and subscapularis tendinitis. The teres minor tendon is intact. There is subdeltoid/subacromial bursal edema.

MUSCLES: No muscle edema or fatty muscle atrophy.

AC JOINT: Intact. There is an anteriorly curved acromion which contributes to rotator cuff impingement.

BICEPS TENDON: Intact long head of the biceps tendon.

LABRUM/LIGAMENTS: There is a tear at the base of the superior glenoid labrum anterior to posterior (SLAP tear).

GLENOHUMERAL CARTILAGE: Intact articular cartilage.

SYNOVIUM/JOINT FLUID: There is small glenohumeral joint fluid.

MARROW: Normal marrow signal. There is enthesopathic subcortical fibrocystic change of the lesser tuberosity of the humerus.

NEUROVASCULAR STRUCTURES: Normal in course and caliber.

PERIPHERAL SOFT TISSUES: Normal.

IMPRESSION:

Linear interstitial tear at the attachment of the subscapularis tendon superimposed on supraspinatus, infraspinatus, and subscapularis tendinitis. Evidence of rotator cuff impingement
