MRI OF THE RIGHT SHOULDER

INDICATION: Pain.

TECHNIQUE: Multiple T1 and T2 weighted MRI images of the right shoulder were obtained in the axial, sagittal and coronal planes without intravenous or intraarticular contrast.

FINDINGS: Motion artifact significantly diminishes sensitivity of this examination. There are no acute displaced fractures, dislocations, destructive bony lesions or marrow infiltration in the proximal humerus and glenoid. The acromioclavicular joint is intact.

The rotator cuff musculature including the supraspinatus, subscapularis, infraspinatus and teres minor are normal in bulk without atrophy, edema or fatty infiltration. The biceps tendon is situated within the bicipital groove and its attachment to the superior labrum is intact. The glenoid labrum is grossly intact. There are no masses associated with the glenohumeral joint.

There is a high-grade partial tear of the distal supraspinatus tendon. There is a high-grade partial tear of the distal subscapularis tendon. There is a partial tear of the distal infraspinatus tendon. Fluid in the subacromial/subdeltoid bursa suggestive of underlying rotator cuff tears and/or subacromial/subdeltoid bursitis, in an appropriate clinical setting. Productive hypertrophic changes of the acromioclavicular joint with impingement of rotator cuff. Mild joint effusion consistent with recent trauma or synovitis, in an appropriate clinical setting.

IMPRESSION:

1. High-grade partial tear of the distal supraspinatus tendon.
2. High-grade partial tear of the distal subscapularis tendon.
3. Partial tear of the distal infraspinatus tendon.
4. Fluid in the subacromial/subdeltoid bursa suggestive of underlying rotator cuff tears and/or subacromial/subdeltoid bursitis, in an appropriate clinical setting.
5. Productive hypertrophic changes of the acromioclavicular joint with impingement of rotator cuff.
