MRI OF THE LEFT KNEE

The posterior cruciate and collateral ligaments appear intact as do the extensor tendons of the knee. The muscles and other tendons of the knee are unremarkable.

The menisci appear intact without suspicious signal changes for a tear.

IMPRESSION:

1. Mild joint effusion.
2. Questionable partial rupture of a previous popliteal cyst without residua.
3. Edema at the superolateral aspect of Hoffa's fat pad consistent with patella tendon lateral femoral condyle friction syndrome.
4. Mild patella alta.
5. Moderate tearing/thinning of the articular cartilage of the central trochlea with signal abnormality in the articular cartilage.
6. Partial tearing of the anterior cruciate ligament with ganglion cyst formation as described and edema within the proximal tibia at the anterior tibial spine at the anterior cruciate ligament attachment.
7. Menisci intact.

Thank you for this referral.
