Dear Dr. Barakat:

MRI OF THE RIGHT SHOULDER

TECHNIQUE: Sagittal T1 weighted spin-echo, T2 weighted fast spin-echo and STIR images were obtained along with coronal T2 weighted fast spin-echo and axial T1 weighted spin-echo and gradient echo images.

FINDINGS: There is mild glenohumeral joint space narrowing marginal osteophyte formation and cartilage thinning. The acromioclavicular joint is hypertrophic without inferior expansion. The acromion is horizontal in orientation. The supraspinatus outlet is patent.

Evaluation of rotator cuff musculature reveals tendinosis of anterior and central fibers of the supraspinatus tendon. There is reactive subchondral cyst formation in the humeral head. Infraspinatus, teres minor and subscapularis muscles are preserved. There is a capsular effusion. There is decompression into the biceps long head tendon sheath. There is axillary recess distension. There is subscapularis recess distension. There is subcoracoid bursal distension. The biceps long head tendon is anatomic in position and is intrinsically intact. The biceps labral anchor is preserved. There is an anteroinferior labral tear.

IMPRESSION:

1. Tendinosis of anterior and central fibers of the supraspinatus.
