LEFT SHOULDER MRI WITHOUT CONTRAST

HISTORY: Left shoulder pain status post motor vehicle accident

TECHNIQUE: Multiplanar, multi-sequence MRI of the left shoulder was performed without intravenous contrast.

COMPARISON: None available.

FINDINGS:

ROTATOR CUFF: There is an interstitial tear at the confluence of the supraspinatus and infraspinatus tendon insertions are superimposed on tendinitis. There is thickening and edema of the subdeltoid/subacromial bursa consistent with bursitis. The subscapularis and teres minor tendons are intact.

MUSCLES: No muscle edema or fatty muscle atrophy.

AC JOINT: There is acromioclavicular joint separation with tearing of the joint capsule. There is thickening of the coracoacromial ligament which contributes to rotator cuff impingement.

BICEPS TENDON: Intact long head of the biceps tendon.

LABRUM/LIGAMENTS: No labral tear.

GLENOHUMERAL CARTILAGE: Intact articular cartilage.

SYNOVIUM/JOINT FLUID: No joint effusion or synovial thickening.

MARROW: Normal marrow signal.

NEUROVASCULAR STRUCTURES: Normal in course and caliber.

PERIPHERAL SOFT TISSUES: Normal.

IMPRESSION:

Interstitial tear at the confluence of the supraspinatus and infraspinatus tendon insertions superimposed on tendinitis. Associated subdeltoid/subacromial bursitis. Evidence of rotator cuff impingement secondary to thickening of the coracoacromial ligament.
