MRI-LEFT KNEE NON CONTRAST

HISTORY: Left knee pain status post MVA

TECHNIQUE: MR imaging of the left knee was performed without IV contrast on a 3.0 Tesla Ultra High Field Wide Bore MRI unit utilizing the following pulse sequences: Sagittal proton density with and without fat suppression, axial proton density fat-suppressed, and coronal proton density fat-suppressed.

COMPARISON: No prior studies are available for comparison.

FINDINGS:

COLLATERAL LIGAMENTS: Edema surrounding the medial collateral ligament compatible with a grade 1 sprain. The lateral collateral ligament, biceps femoris tendon, iliotibial band, and popliteus tendon are intact.

CRUCIATE LIGAMENTS: The anterior and posterior cruciate ligaments are intact.

MENISCI: The medial meniscus is intact. The lateral meniscus are intact.

CARTILAGE:

The chondral surfaces in the medial compartment are intact  
The chondral surfaces in the lateral compartment are intact  
The chondral surfaces in the anterior compartment are intact.

BONES: The visualized osseous structures demonstrate normal bone marrow and cortical signal intensity without evidence of fracture, trabecular bone injury or dislocation. No osseous lesions are identified.

EXTENSOR MECHANISM: The quadriceps and patellar tendons are normal.

JOINT: There is a joint effusion. The soft tissues are otherwise normal.

The neurovascular structures demonstrate normal course.

**IMPRESSION:**

Grade 1 sprain of the medial collateral ligament.

Joint effusion.

Intact medial and lateral meniscus.
