RIGHT SHOULDER MRI WITHOUT CONTRAST

HISTORY: Right shoulder pain status post motor vehicle accident

TECHNIQUE: Multiplanar, multi-sequence MRI of the right shoulder was performed without intravenous contrast.

COMPARISON: None available.

FINDINGS:

ROTATOR CUFF: There is a high-grade interstitial tear at the attachment of the supraspinatus tendon. There is an additional interstitial tear of the distal infraspinatus tendon. There is supraspinatus and infraspinatus tendinitis. The subscapularis and teres minor tendons are intact. There is subdeltoid/subacromial bursal fluid and edema consistent with bursitis.

MUSCLES: No muscle edema or fatty muscle atrophy.

AC JOINT: There is moderate acromioclavicular joint disease with capsular thickening. There is thickening of the coracoacromial ligament which contributes to rotator cuff impingement.

BICEPS TENDON: Intact long head of the biceps tendon.

LABRUM/LIGAMENTS: No labral tear.

GLENOHUMERAL CARTILAGE: Intact articular cartilage.

SYNOVIUM/JOINT FLUID: No joint effusion or synovial thickening.

MARROW: Normal marrow signal. There is subcortical fibrocystic change and marrow edema signal at the greater tuberosity of the humerus.

NEUROVASCULAR STRUCTURES: Normal in course and caliber.

PERIPHERAL SOFT TISSUES: Normal.

IMPRESSION:

High-grade interstitial tear at the attachment of the supraspinatus tendon. Additional interstitial tear of distal infraspinatus tendon. Background of supraspinatus and infraspinatus tendinitis. Associated subdeltoid/subacromial bursitis.

DOB: 04/13/1968

Gender: M

MRN: LewS5111

Evidence of rotator cuff impingement secondary to thickening of the coracoacromial ligament.
Moderate acromioclavicular joint disease.
