Dear Dr. Gelb:

MRI OF THE LEFT SHOULDER

TECHNIQUE: Sagittal T1 weighted spin-echo, T2 weighted fast spin-echo and STIR images were obtained along with coronal T2 weighted fast spin-echo and axial T1 weighted spin-echo and gradient echo images.

FINDINGS: There is posterosuperior and central migration of the humeral head. There is limited acromioclavicular joint hypertrophy impinging upon the supraspinatus musculotendinous junction. The acromion is horizontal in orientation.

Evaluation of rotator cuff musculature reveals tendinosis of anterior fibers of the supraspinatus tendon. Infrapinatus, teres minor and subscapularis muscles are preserved. There is a capsular effusion. There is decompression into the biceps long head tendon sheath. There is axillary recess distension. There is subcoracoid bursal distension. The biceps long head tendon is anatomic in position and is intrinsically intact. The biceps labral anchor is preserved. There is a posterior inferior quadrant labral tear.

IMPRESSION:

1. Tendinosis of anterior fibers of the supraspinatus.
