Dear Dr. Coburn:

MRI OF THE RIGHT ELBOW

Multipolar, multisequence, multiecho MRI examination was performed through the right elbow without intravenous contrast using a low field MRI.

The bony structures are well aligned. There is a tiny benign appearing subcortical cyst posterior to the capitulum, in the distal humerus. There is no acute fracture, suspicious intrinsic lesion or evidence of osteonecrosis.

The articular cartilages appear preserved.

There is no significant joint effusion.

There is a partial tear of the common extensor tendon at the lateral epicondyle. There is partial tearing of the adjacent radial collateral ligament at the humeral attachment.

The biceps, triceps, brachialis, and common flexor tendons appear intact.

No ligamentous disruptions are appreciated.

The ulnar nerve is unremarkable.

No masses or collections are identified.

MRI OF THE RIGHT ELBOW

IMPRESSION:

1. Partial tear of the common extensor tendon at the lateral epicondyle.
2. Partial tear of the radial collateral ligament at the humeral attachment.

Thank you for this referral.
