MAGNETIC RESONANCE IMAGING OF THE LEFT SHOULDER

TECHNIQUE: Multiplanar, multisequential MRI was performed in the recumbent position.

HISTORY: The patient complains of left shoulder pain with numbness, weakness and moderate effect on arm movement due to work injury.

INTERPRETATION: The supraspinatus and infraspinatus tendons demonstrate tendinosis/tendinopathy with diffuse intrasubstance signal abnormality distally.

Trace fluid tracking within the long head biceps tendon sheath consistent with tenosynovitis.

Hypertrophic changes of the AC joint and ventrally downsloping acromion which abuts the bursal surface of the rotator cuff.

Benign-appearing cyst measuring 6 mm posteriorly within the proximal humeral metaphysis.

Examination otherwise demonstrates the osseous structures of the shoulder to be otherwise unremarkable in signal and morphology. Muscular and tendinous structures including remaining portions of the rotator cuff are also felt to remain otherwise unremarkable in signal and morphology. The glenoid labrum and bicipital tendon otherwise appear unremarkable in position and morphology.

IMPRESSION:

- Supraspinatus and infraspinatus tendons demonstrate tendinosis/tendinopathy with diffuse intrasubstance signal abnormality distally.
- Trace fluid tracking within the long head biceps tendon sheath consistent with tenosynovitis.

- Hypertrophic changes of the AC joint and ventrally downsloping acromion which abuts the bursal surface of the rotator cuff.

Thank you for referring your patient to us for evaluation.

Sincerely,

Ronald Wagner, M.D.
