**RIGHT SHOULDER MRI WITHOUT CONTRAST**

**HISTORY:** Right shoulder pain status post motor vehicle accident

**TECHNIQUE:** Multiplanar, multi-sequence MRI of the right shoulder was performed without intravenous contrast.

**COMPARISON:** None available.

**FINDINGS:**

**ROTATOR CUFF:** There is an interstitial tear at the attachment of the infraspinatus tendon superimposed on supraspinatus, infraspinatus, and subscapularis tendinitis. The teres minor tendon is intact. There is subdeltoid/subacromial bursal thickening and edema consistent with bursitis.

**MUSCLES:** No muscle edema or fatty muscle atrophy.

**AC JOINT:** There is severe acromioclavicular joint disease with capsular thickening and marginal osteophytes which exert mass-effect on the supraspinatus myotendinous junction. There is additional anterolateral downsloping of the acromion which also contributes to rotator cuff impingement.

**BICEPS TENDON:** Intact long head of the biceps tendon.

**LABRUM/LIGAMENTS:** There is a tear of the anterior superior to posterior superior glenoid labrum (SLAP tear) with a partial tear of the biceps labral anchor complex.

**GLENOHUMERAL CARTILAGE:** Intact articular cartilage.

**SYNOVIUM/JOINT FLUID:** There is a glenohumeral joint effusion.

**MARROW:** Normal marrow signal.

**NEUROVASCULAR STRUCTURES:** Normal in course and caliber.

**PERIPHERAL SOFT TISSUES:** Normal.

**IMPRESSION:**

Tear of the anterior superior to posterior superior glenoid labrum (SLAP tear) with a partial tear of the biceps labral anchor complex. Associated glenohumeral joint effusion.

Interstitial tear at the attachment of the infraspinatus tendon superimposed on infraspinatus, supraspinatus, and subscapularis tendinitis. Associated subdeltoid/subacromial bursitis. Evidence of rotator cuff impingement secondary to severe acromioclavicular joint disease and anterolateral downsloping of the acromion.
