Dear Dr. Barakat:

MRI OF THE LEFT SHOULDER

Multiplanar, multisequence, multiecho MRI examination was performed through the left shoulder without intravenous contrast using a low field MRI.

The humeral head is superiorly positioned in relationship to the glenoid. The articular cartilages of the glenohumeral joint appear preserved.

There is a mostly straight, slightly low-positioned acromion process with an intact acromioclavicular joint. There is no significant subacromial impingement.

There is no acute fracture, suspicious intrinsic lesion, or evidence of avascular necrosis.

The muscles and tendons of the rotator cuff appear intact without suspicious signal changes for a tear.

The long head of the biceps tendon appears intact.

There is a posterior labral tear crossing from superior to inferior without significant displacement.

There is no significant joint effusion nor significant fluid/synovitis of the subacromial or subdeltoid bursa.

MRI OF THE LEFT SHOULDER

IMPRESSION:

1. Posterior labral tear.
2. Humeral head superiorly positioned in relationship to the glenoid.
3. Muscles and tendons of the rotator cuff intact.

Thank you for this referral.
