Gender: M
MRN: OluO5390

RIGHT SHOULDER MRI WITHOUT CONTRAST

HISTORY: Right shoulder pain status post motor vehicle accident

TECHNIQUE: Multiplanar, multi-sequence MRI of the right shoulder was performed without intravenous contrast.

COMPARISON: None available.

FINDINGS:

ROTATOR CUFF: There is an interstitial tear at the attachment of the Infraspinatus tendon best seen on image 22 of the sagittal series. There is reactive subcortical marrow edema signal at the greater tuberosity of the humerus. There is supraspinatus and infraspinatus tendinitis. The subscapularis and teres minor tendons are intact.

MUSCLES: No muscle edema or fatty muscle atrophy.

AC JOINT: Intact. There is lateral downsloping of the acromion with subacromial spurring and thickening of the coracoacromial ligament which contribute to rotator cuff impingement. There is associated subdeltoid/subacromial bursal thickening and edema indicative of bursitis.

BICEPS TENDON: Intact long head of the biceps tendon.

LABRUM/LIGAMENTS: No labral tear.

GLENOHUMERAL CARTILAGE: Intact articular cartilage.

SYNOVIUM/JOINT FLUID: No joint effusion or synovial thickening.

MARROW: Normal marrow signal.

NEUROVASCULAR STRUCTURES: Normal in course and caliber.

PERIPHERAL SOFT TISSUES: Normal.

IMPRESSION:

Interstitial tear at the attachment of the infraspinatus tendon superimposed on infraspinatus and supraspinatus tendinitis. Evidence of rotator cuff impingement secondary to lateral downsloping
