Dear Dr. Barakat:

MRI OF THE LEFT SHOULDER

An MRI examination of the left shoulder was performed in multiple planes, and multiple sequences were obtained.

The humeral head is mildly superiorly positioned in relationship to the glenoid. The glenohumeral joint articular cartilages appear preserved.

There is a slightly curved acromion process with mild to moderate hypertrophic changes of the acromioclavicular joint. This is causing a mild degree of subacromial impingement upon the muscular tendinous junction of the supraspinatus.

Benign appearing subcortical cystic changes are observed in the lesser tuberosity near the articular surface. There is no acute fracture, suspicious intrinsic lesion, or evidence of avascular necrosis.

There is a partial tear of the distal supraspinatus tendon favoring the anterior fibers. There is partial tearing and tendinosis of the infraspinatus tendon without retraction. There teres minor and subscapularis tendons appear intact as does the long head of the biceps tendon.

There is mild atrophy of the teres minor muscle. There is no definite mass or other abnormality noted within the quadrilateral space. Clinical correlation is recommended. The muscles are otherwise unremarkable.

There is a mild to moderate amount of fluid/synovitis of the subacromial and subdeltoid bursa, located mostly anteromedially. There is a trace glenohumeral joint effusion.

No labral tears are appreciated.

MRI OF THE LEFT SHOULDER

IMPRESSION:

1. Partial tear of the supraspinatus tendon favoring the anterior fibers.
2. Partial tear and tendinosis of the infraspinatus tendon.
3. Humeral head mildly superiorly positioned in relationship to the glenoid.
4. Mild to moderate hypertrophic changes of the acromioclavicular joint causing a mild degree of subacromial impingement upon the musculotendinous junction of the supraspinatus.
5. Mild to moderate amount of fluid/synovitis of the subacromial and subdeltoid bursa, most prominent anteriorly.

Thank you for this referral.
