Dear Dr. Barakat:

MRI OF THE RIGHT SHOULDER

TECHNIQUE: Sagittal T1 weighted and T2 weighted fast spin-echo and STIR images were obtained. Coronal T2 weighted fast spin-echo images were obtained. Axial T1 and T2 weighted fast spin-echo images were obtained.

FINDINGS: There is superior and central migration of the humeral head with abutment of the inferior surface of a broad horizontal acromion. There is glenohumeral joint space narrowing with cartilage thinning. There is **acromioclavicular** osteoarthritis with inferior marginal osteophyte formation impinging upon the supraspinatus outlet.

Evaluation of rotator cuff musculature reveals a full thickness full width tear of the supraspinatus tendon which retracts as far proximal as the acromioclavicular joint yielding a diastasis of 6.0 cm. There is proximal supraspinatus atrophy. There is a full thickness tear of the infraspinatus tendon retracted as far proximal as the mid acromion yielding a diastasis of 4.7 cm. Teres minor and subscapularis insertions are preserved. There is a capsular effusion. There is anatomic decompression into the subacromial-subdeltoid bursa. There is an anteroinferior labral tear with inferior labral extension. There is truncation of the posterior superior labrum with an associated subcentimeter paralabral cyst.

IMPRESSION:

1. Supraspinatus and infraspinatus full thickness tearing with marked retraction.
