SERVICE:	MRI LEFT KNEE
DATE OF SERVICE:	11/04/2022

MRI SCAN OF THE LEFT KNEE

HISTORY: History of MVA.

TECHNIQUE: Non-contrast MRI of the left knee was performed utilizing multiplanar and multisequence acquisition.

FINDINGS:

There is joint fluid compatible with synovitis. Soft tissue edema is present anterior to the anterior tibial tubercle and patellar ligament insertion. There is no evidence of popliteal cyst formation or muscular tear. There is no evidence of fracture, dislocation, or bone marrow abnormalities to be suspicious for bone contusions, stress fractures, or acute trabecular microfractures.

The anterior and posterior cruciate ligaments as well as the medial and lateral collateral ligament complexes appear intact.

The popliteal and quadriceps tendons and the patellar ligament are unremarkable. The patellar retinacula are intact.

A single image demonstrates a linear hyperintense signal extending to the superior articular surface of the posterolateral meniscal horn. Since the finding is only seen on a single image, this is consistent with a Grade 2B signal (from the literature, 50% are positive for tears) and compatible with a posterolateral meniscal tear.

In addition, there is a linear hyperintense signal extending to the superior articular surface of the posteromedial meniscal horn seen on a single image consistent with Grade 2B signal/posteromedial meniscal tear.

The medial and lateral meniscal structures are otherwise intact. No other meniscal tears are suspected.

IMPRESSION:

Presence of joint fluid compatible with synovitis and soft tissue edema anterior to the anterior tibial tubercle and patellar ligament insertion.

Findings compatible posteromedial meniscal tear as well as posterolateral meniscal tear as discussed in the body of the report.

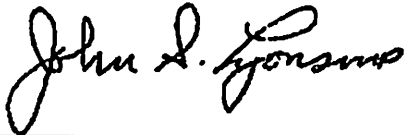

The anterior and posterior cruciate ligaments as well as the medial and lateral collateral ligament complexes appear intact.
