Dear Dr. Kopach:

MRI OF THE LEFT SHOULDER

TECHNIQUE: Sagittal T1 weighted and T2 weighted fast spin-echo and STIR images were obtained. Coronal T2 weighted fast spin-echo images were obtained. Axial T1 and T2 weighted fast spin-echo images were obtained.

FINDINGS: There is limited posterosuperior and central migration of the humeral head. The acromioclavicular joint is not hypertrophic. There is a horizontal acromion with minimal inferior enthesophyte formation impinging upon the supraspinatus musculotendinous junction.

Evaluation of rotator cuff musculature reveals no loss of integrity. Supraspinatus, infraspinatus, teres minor and subscapularis tendinous insertions are preserved. There is minimal subacromial-subdeltoid bursitis. There is a capsular effusion with anatomic decompression into the biceps long head tendon sheath, limited in degree. There is axillary recess distension. The biceps longus tendon is anatomic and is intrinsically intact. The biceps anchor is preserved. There is an anteroinferior labral tear (series 7 images 15 and 16).

IMPRESSION:

1. Minimal reactive subacromial-subdeltoid bursitis.
