Exam: CT-RIGHT HIP NON
CONTRAST | 73700

CT-RIGHT HIP NON CONTRAST

History: Right hip pain

Comparison Studies: None

Technique: Multislice helical CT imaging of the right hip was performed, and multiplanar reformat images were created from the primary data sets. This study was performed using automatic exposure control (radiation dose reduction software) to obtain a diagnostic image quality scan with patient dose as low as reasonably achievable. The administered radiation dose was 2.61 mSv.

Findings:

The skin and subcutis are unremarkable.

The visualized neurovascular structures are unremarkable in CT appearance.

The visualized muscle-tendon units are unremarkable in CT appearance.

No joint effusion is visualized.

No bursal effusion is visualized.

Mild to moderate joint space narrowing the right hip joint with spurring in the lateral acetabulum.

There is no evidence of stress injury, fracture, osteonecrosis or osseous neoplasm.

Bone density is qualitatively normal.

No soft tissue mass is visualized.

No ganglion cyst, abscess, hematoma or other extra-articular fluid collection is

visualized.

The visualized pelvic visceral structures are unremarkable in noncontrast CT appearance.

Impression:

1. Mild to moderate osteoarthritis in the right hip joint.
2. No fractures.
