Dear Dr. Kopach:

MRI OF THE LEFT SHOULDER

Multiplanar, multisequence, multiecho MRI examination was performed through the left shoulder without intravenous contrast using a low field MRI.

The humeral head is well positioned within the glenoid. The glenohumeral joint appears intact.

There is a slightly curved, mildly laterally downsloping acromion process with an intact acromioclavicular joint. There is no significant subacromial impingement.

There is no fracture, suspicious intrinsic lesion, or evidence of osteonecrosis.

There is a partial tear of the distal supraspinatus tendon favoring at the footprint without retraction. The infraspinatus, teres minor, and subscapularis tendons appear intact as does the long head of the biceps tendon.

There is a mild to moderate amount of fluid/synovitis of the subacromial and subdeltoid bursa. There is a mild amount of fluid in the subcoracoid region which appears to be within the subscapular bursa. There is no significant glenohumeral joint effusion.

No labral tears are appreciated on these images.

MRI OF THE LEFT SHOULDER

IMPRESSION:

1. Partial tear of the distal supraspinatus tendon.
2. Mild to moderate amount of fluid/synovitis of the subacromial and subdeltoid bursa.
3. Mild amount of fluid in the subcoracoid region which appears to be within the subscapular bursa.

Thank you for this referral.
