### MRI OF THE RIGHT SHOULDER WITHOUT CONTRAST

INDICATION: Right shoulder pain

COMPARISON: No prior study was available for comparison at the time of dictation.

TECHNIQUE: T1, T2, and PD, axial, coronal, and sagittal sequences were obtained.

#### FINDINGS:

No fracture or suspicious lesion. No os acromiale or intra-articular loose body. No evidence of significant arthritis and glenohumeral cartilage grossly intact.

There is a low-lying acromion also impinging on predominantly supraspinatus. Both infraspinatus, supra spinous tenderness is noted, with broad bursal surface fraying extending from the conjoined region anteriorly along the supraspinatus, and at the anterior insertional fibers there is a more distinct suggestive articular surface tear with subtendinous fluid. Series 5 image 10. ACR arthrosis and mild subacromial bursitis.

Small glenohumeral fluid, suspicion of underlying anterosuperior labral tear 2:00 axis. Biceps tendinopathy with proximal peritendinous fluid and mild tenosynovitis. Intact superior glenohumeral ligament. Intact biceps labral anchor complex.

The inferior glenohumeral ligament is intact. Teres minor tendon is normal. No muscle atrophy.

No significant effusion. No intra-articular loose body.

#### IMPRESSION:

1. Suggestive shoulder impingement predominantly on the supraspinatus. fraying extending from the conjoined region anteriorly along the supraspinatus, and at the anterior insertional fibers there is a more distinct suggestive articular surface tear with subtendinous fluid. Series 5 image 10. ACR arthrosis and mild subacromial bursitis.
