LEFT SHOULDER MRI WITHOUT CONTRAST

HISTORY: Left shoulder pain status post motor vehicle accident

TECHNIQUE: Multiplanar, multi-sequence MRI of the left shoulder was performed without intravenous contrast.

COMPARISON: None available.

FINDINGS:

ROTATOR CUFF: There is an interstitial tear at the attachment of the infraspinatus tendon superimposed on infraspinatus and supraspinatus tendinitis. The subscapularis and teres minor tendons are intact. There is prominent thickening and edema of the subdeltoid/subacromial bursa consistent with bursitis.

MUSCLES: There is feathery edema within the acromial head of the deltoid muscle consistent with muscle strain.

AC JOINT: There is mild acromioclavicular joint disease with capsular thickening and marginal osteophytes. There is anterolateral downsloping of the acromion which contributes to rotator cuff impingement.

BICEPS TENDON: Intact long head of the biceps tendon.

LABRUWLIGAMENTS: There is a tear of the anterior superior glenoid labrum.

GLENOHUMERAL CARTILAGE: Intact articular cartilage.

SYNOVIUM/JOINT FLUID: No joint effusion or synovial thickening.

MARROW: Normal marrow signal.

NEUROVASCULAR STRUCTURES: Normal in course and caliber.

PERIPHERAL SOFT TISSUES: Normal.

IMPRESSION:

Tear of the anterior superior glenoid labrum,

Interstitial tear at the attachment of the infraspinatus tendon superimposed on infraspinatus and supraspinatus tendinitis. Associated subdeltoid/subacromial bursitis. Evidence of rotator cuff impingement secondary to anterolateral downsloping of the acromion.

Strain of the acromial head of the deltoid muscle.
