MRI OF THE RIGHT SHOULDER WITHOUT CONTRAST

HISTORY: Patient was involved in a motor vehicle accident and now complains of pain.

COMPARISON: None.

TECHNIQUE: MRI of the right shoulder was performed using T1 and T2 weighted sequences in multiple planes.

FINDINGS:

Subtle hyperintense signal is seen in the terminal portion of supraspinatus tendon on T1 weighted images, suggestive of tendinosis. Other rotator cuff tendons appear unremarkable. There is no evidence of tendon tear.

Mild degenerative changes are detected in the acromio-clavicular joint. There is mild lateral downsloping of the acromion.

Mild synovial effusion is seen. Mild fluid is seen in subacromial – subdeltoid, subcoracoid bursae and along the biceps tendon.

There is mild thickening of inferior glenohumeral ligament.

The alignment of the shoulder joint is normal. The bones around the shoulder joint reveal normal intensity.

The gleno-humeral joint is normal. There is no evidence of erosion or destruction of articular cartilage. The articular margins are intact.

The glenoid labrum is normal.

The muscles and their attachments also appear normal. Major neurovascular bundles are normal.

IMPRESSION:

1. Tendinosis of the supraspinatus tendon.

- 2. Mild degenerative changes in the acromio-clavicular joint.
- 3. Mild lateral downsloping of the acromion.
- 4. Mild synovial effusion.
- 5. Mild fluid in subacromial subdeltoid, subcoracoid bursae and along the biceps tendon.
- 6. Mild thickening of inferior glenohumeral ligament.

Thank you for the courtesy of this referral.
