JORDAN FERSEL, MD

## MRI EXAM OF THE RIGHT SHOULDER WITHOUT CONTRAST

INDICATION: PAIN.

TECHNIQUE: MRI exam of the right shoulder was performed in sagittal, coronal and axial planes using T1 and T2-weighted sequences.

**COMPARISON:** There are no prior exams for comparison.

FINDINGS: There has been prior surgery with metallic pins transfixing the greater tuberosity of the humerus. No fracture is seen. There is osteophyte formation at the acromioclavicular joint.

There is abnormal signal intensity in the distal portion of the supraspinatus tendon consistent with tear. There is no retraction of the tendon. There is fluid in the subacromium and subdeltoid bursa and the findings are consistent with tendinopathy. There is tendinopathy and tear of the infraspinatus and teres minor tendons with atrophic changes in the associated muscles. There is tendinopathy of the subscapularis tendon.

The glenohumeral joint is maintained. There is irregularity of the articular margins without evidence labral tear. There is a joint effusion.

## **IMPRESSION:**

- 1. Prior surgery for rotator cuff tear with metallic screws in the greater tuberosity of humerus; osteophytes at the acromioclavicular joint.
- 2. Tendinopathy of the supraspinatus tendon; no evidence of retraction.
- 3. Tendinopathy of the infraspinatus, teres minor and subscapularis tendons as noted above.
- 4. Irregularity of the articular margins of the glenohumeral joint without labral tear; joint effusion.

Thank you for the opportunity to participate in the care of this patient.
